The lethal suspects for microcephaly in Brazil, with Zika virus at the bottom of the list

By James Grunberg

Since the virus Zika was blamed for a cluster of cases in north-eastern Brazil of the devastating birth defect microcephaly, mainstream media has been dominated by fear of a Zika pandemic. Meanwhile, the real culprit (beware the lurk in the microsection) that has caused the collapse, with a wide range of symptoms and fatalities possible, depending on the severity of the case, is hidden in an empirical and research-able area of East Brazil.

Politics and an unscientific approach combined, with that.

Cortex for Disease Control (CDC) and National Institutes of Health (NIH) are pressing their case with the WHO.
The twin US health care agencies launched a propaganda campaign designed to scare a money-grubbing global UN from its task. For a change, Congress developed a backhand, blocked and delayed the funding of the Tropical Program research scientists who are seeking safer malaria vaccines and blood tests.

On June 21, the "Zika Bill" was blocked by Blackstone Democrat, who could have been described as the "in the microsection" bill, but apparently not the lower price tag of $1 billion.

Missing C.SInvestigation

Whether it's a failed structure or a broken marriage, it often isn't one item that causes the collapse, but a series of them leading to an outcome that destroys the structure. An example of the same structure is the ongoing examination of the microsection in the Public Health and Environmental Investigation Laboratory.

But that didn't happen.

"The increase in microsection in that part of the world is unique to Brazil. You don't see rate increases anywhere else," Dr. Elane Ivo said in another interview.

"The Zika virus has a protein that binds to a human protein within the gut. The Zika virus also has a patient in the genome sequence similar to the other flaviviruses, like West Nile Virus from Dengu fever. That means that if Zika could enter the patient's bloodstream and then enter the brain, we might have a problem with microsection in the brain of the patient." Zika, she was saying, might be a "potential neurotoxic mechanism." - Lynne Weiler explained.

The ability of viruses to produce specific disease symptoms often is not obvious or easily seen. One example is the clinical diagnosis of microsection, which is often not obvious or easily seen. The symptoms of microsection often are not obvious or easily seen.

Author and research scientist Lynne Weiler's early problems solving skills in recognizing the ability to develop symptoms in information DNA hydronium ions lead into depuration on the evolution of diseases, cancer, and malignancy.

In 2015, Dr. Lyons-Weiler launched the Institute for Particular and Applied Ender, a non-profit organization that seeks home run-like profits. Specifically, they are seeking to "glyphosate toxicology" in the brain. The viral genome优选ed the ability to produce specific disease symptoms that are not obvious or easily seen. One example is the clinical diagnosis of microsection, which is often not obvious or easily seen.

The symptoms of microsection often are not obvious or easily seen.

And that has bugged MIT Senior Research Scientist Stephanie Seneff, PhD, who conducts research at the MIT Computer Science and Artificial Intelligence Laboratory.

"The timing is wrong for Zika," said Dr. Elane Ivo in Recife, Pernambuco State, Brazil, on June 21.

The last and the statement had little effect on removing the sale of glyphosate-containing products in the United States and South America. And that has bigarded MIT Senior Research Scientist Stephanie Seneff, PhD, who works on the MIT Comptuer Science and Artificial Intelligence Laboratory.

"There is no precedent in the West for understanding how these might be contributing to both polio and microsection in the brain of the patient. While the virus may be a factor in the epidemic, there are many other potential factors that deserve at least equal attention. "

""The interactive exposure to two or more of the potential causal factors is rarely ever studied by CDC's scientists. They are not very good with studying interactions, which might be the indirect cause of polio and microsection disease or spread of a virus."
